Addition of phenols to alcohols is less exothermic than expected based on the positive value of the steric constant (σ(C-O)). Calculations on an idealized phenol and a series of simple alcohols illustrate this effect, the strength of which depends on the substituted group and the length of the alkoxy substituent. We propose that phenols react with alcohols through a [3,3]-O-O cleavage mechanism, rather than through a nucleophilic attack on the oxygen atom. The higher energy for O-O cleavage is due to the lower pK(a) of the oxygen atom. The O-Steric Effect is a driving force for the formation of the more stable phenol-alcohol adduct. This work may be a first step in a mechanism to understand the reactivity of phenols in biological systems.Asa Matthews Asa Matthews is an American theatre director, dance instructor, and choreographer who is best known for his work with both the American Ballet Theatre and American Ballet Theatre School.
