Myocardial uptake of ^{201}Tl as a marker of early myocardial damage after experimental infarction. To assess the changes in myocardial uptake of ^{201}Tl after experimental infarction, the time-activity curve of ^{201}Tl after the injection of the tracer was determined with a scintillation camera in 24 closed-chest dogs. A balloon-occlusion technique was used to produce anterior myocardial infarction. After infarction, the distribution of tracer activity was assessed with a scintillation camera at early (1 day) and late (4 days) stages after infarction. In all animals, the cardiac uptake of ^{201}Tl at 1 and 4 days after infarction was higher than the background activity, which was determined in healthy dogs. On day 1, the peak of the time-activity curve at the anterior myocardial infarction area was detected earlier than in the normal myocardium. At late stages, the uptake of tracer in the anterior myocardial infarction area tended to decrease but remained higher than the background activity. To evaluate the regional myocardial perfusion, a hemodynamically equivalent region was defined, and the count-density per myocardial volume was calculated. There was no significant correlation between the uptake of ^{201}Tl and the regional myocardial perfusion, except for the washout rate. The invention relates generally to improving network performance in a communication network having a number of different customer networks. More particularly, the invention relates to the monitoring of a number of different types of metrics from different types of data sources to determine the amount of time that is required to provide a connection to a particular customer, and then determining whether that time is within a specific acceptable range. A typical communications network provides point-to-point communications between a number of different network components (customer networks, operator networks, and control networks) and a number of different types of traffic (voice, data, video, and so forth). Typically, in networks that use circuit switching techniques, a connection is established between two customer networks, and then that connection is maintained until the connection is explicitly torn down. This type of connection is sometimes referred to as a "hard" connection. Alternatively, in networks that use packet switching techniques, a connection is established between two customer networks, and the connection is maintained until the customer networks are no longer communicating or the connection is explicitly torn down. This type of connection is sometimes referred to as
